ABSTRACT: The present study entitled "Effect of environmental conditions on biometric parameters and yield of broccoli" was carried out at the Experimental farm of the Department of Environmental Science, Dr. Yashwant Singh Parmar University of Horticulture and Forestry, Nauni, Solan, Himachal Pradesh during Rabi 2021-22. In mid hills occurrence of fog is common, thus it is necessity to study the growth of broccoli under different environmental conditions as the yield potential of broccoli is more in the rabi season. The results revealed that treatment (T2M1I1) i.e., Mid-season transplanting (28th Oct) + Mulch + Irrigation recorded significantly higher on biometric parameters *i.e.*, Biometric attributes *i.e.*, Chlorophyll content (2.23 mg/g) and Leaf area index (5.10) showed significant highest values in treatment  $(T_2M_1I_1)$ Micrometeorological parameter i.e., Evapotranspiration (2.48mm/day) was found in treatment (T<sub>2</sub>M<sub>1</sub>I<sub>1</sub>). Plant canopy relative humidity and Soil moisture were also recorded. Agroclimatic indices i.e., Crop phenology of 132 days were observed. Growing degree days of 140.10 days/hrs were accumulated in T<sub>2</sub>. Heliothermal units of 7248.74 days/hours were observed in T<sub>2</sub>, Photo-thermal units of 10031.55 days/hrs were observed and, yield (10.44kg) per plot was observed in the treatment of T2M1I1. Treatment T2M1I1 is recommended for improving biometric attributes, micrometeorological parameters, agroclimatic indices, and yield attributes in Broccoli. Among different environmental conditions mulching and irrigation played an important role in the physiological and morphological characteristics of broccoli thus enhancing the crop yield.

Keywords: Chlorophyll, evapotranspiration, heat indices, Growing Degree Day, Helio-thermal Unit, Thermal Use Efficiency, leaf area index.

# **INTRODUCTION**

Broccoli (Brassica oleracea var italica L.) is one of the most popular annual crops but a seed production purpose biennial crop in the Brassicaceae family. It is closely related to the "rapeseed crop group", with chromosome number of 2n=18. Broccoli is native to the Mediterranean region. The period of variation of broccoli derived from the is Latin word Brachium, meaning an arm or department Kumar et al. (2014). Botanically, it is classified as a distribution of Brassica oleracea which grows throughout the winter. The time period 'microgreens' has no prison definition however is used by marketers to explain a particular product class Palmitessa et al. (2022). Broccoli is a cross-pollinated crop. It is a highly nutritious crop with excellent dormancy, often attributed to high levels of vitamins (A, B, and C), minerals (K, P, Ca, and Fe), metabolites (omega-3 fatty acids), and fiber. That is why it is also called "the crown jewel of nutrition. It is an excellent source of indole, folic acid, sulforaphane, and glucosinolates. In India, broccoli occupies nearly 4.5 lakh hectares of area with a production of 8.8 metric tons and productivity of 1.9 kg per ha (FAOSTAT, 2020). High consumption of broccoli has been shown to reduce the risk of cancer because it contains the compound sulforaphane and can also protect against heart diseases (Allen and Allen 2007).

Broccoli is widely grown in China, India, the USA, Spain, Mexico, Italy, and other parts of the world. In India, it is commonly grown in the Nilgiri Hills, Himachal Pradesh, Uttar Pradesh, Jammu, and Kashmir and is often referred to as 'green shoot broccoli' or 'Calabria' or 'hari gobhi of the northern plains. India is the second largest producer of broccoli after China. China and India together account for more than 75% of the world's total broccoli production. Broccoli grows best when the average daily temperature is between 17 and 23°C. Temperatures below the optimum range slow down ripening and lead to small buds. In addition, it does not tolerate high temperatures because it produces poor-quality bean sprouts (Anonymous, 2013). For irrigation scheduling and effective water management. an accurate estimation of evapotranspiration is required (López -Urrea et al., 2009). However, factors that affect evapotranspiration such as humidity, solar radiation, wind speed, crop growth stages, and type of soils and their hydraulic and physical properties vary both in space and time. Evapotranspiration can be seen as an integrated response to all these factors and a major contributor to irrigation requirements. Plant cover greatly affects water use rates. Ritchie and Burnett (1968) found that a leaf area index of about 2.7 is required for water use equal to the potential rate for row crops. The green colour of the broccoli is due to the presence of chlorophyll a and chlorophyll b. Although the chlorophyll contents are measured on a fresh weight basis, the decline in water content is relatively consistent during the sampling period (Christ and Hortisteiner 2014). Among unique mulching treatments used during the heading and harvesting stages, the highest soil moisture and highest quality temperature with low evaporation and minimal warmness loss from the surface soil were observed with the black poly mulch remedies (Sharma, 2009). By mulching, the exposed part of the soil is the hole from where the vegetable plants grow upward. It prevents the loss of water in the soil by evaporation and makes it available to the surrounding environment of the plant root zones for promoting the soil microbial activities (He et al. 2021).

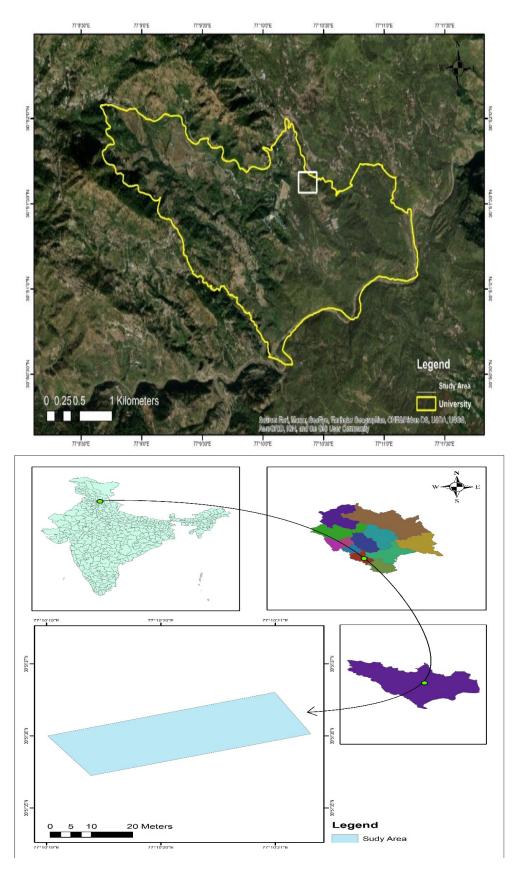

Temperature-based agrometeorological heat indices such as Growing Degree Day (GDD), Helio-thermal Unit (HTU), and Thermal Use Efficiency (TUE) are very useful for predicting the growth and yield of crops. The growing degree day is a simple tool to find out the relationship between plant growth, maturity, and mean air temperature. A degree day or a heat unit is the departure from the mean daily temperature above the minimum threshold temperature (Basu et al., 2012). GDD requirement indicates the thermal status for the onset of a particular phenophase in the crop. The requirement of cumulative GDD is regulated by the ambient temperature as well as changes in the physiological stage of the crop regulated by hormonal activities (Nath et al., 1999). Knowledge of accumulated GDD may project the developmental stages of a crop as well as its approximate date of harvest (Ketring and Wheles 1989; Bonhomme, 2000; Roy et al., 2005). Soil moisture and temperature play an important role in plant growth and development that should remain at optimal levels during different stages of the growing crop plants. The commercial production of broccoli is an emerging challenge in the changing environmental conditions that makes it difficult for farmers to cultivate broccoli appropriately due to the lack of information to overcome these challenges.

Due to climate change, the occurrence of fog in low hills and plains is common, affecting the crop boom throughout the winter. In the middle hills, the occurrence of fog is not uncommon, so he moved to the need to look at the growth of broccoli under environmental conditions because the yield capacity of broccoli is more in the rabi season.

#### MATERIALS AND METHODS

#### A. Experiment site and Climate

The present field experiment on broccoli crops was conducted at the Research Farm Department of Environmental Science, College of Forestry, Dr. Yashwant Singh Parmar University of Horticulture and Forestry, Nauni, Solan, Himachal Pradesh. The area is situated at 30.86°N latitude and 77.17°E longitude an altitude of 1275m above the mean sea level. The climate of the area is sub-tropical to sub-temperate and sub-humid characterized by cold winters and experiences distinguished major seasons in the year. The winter season commences from November to February and ends in March, summer season is from March to June followed by the monsoon period from July to September. The annual normal of maximum and minimum temperature, relative humidity, and rainfall of the area is 25.3°C, 11.4°C, 61 percent, and 111.9 cm, respectively.

Source: Based on the GIS location **Fig. 1.** Location and field layout of the experimental farm.

#### B. Experimental methodology

The soils of the experimental field were brown in colour with a sandy loam texture. There were moderate drainage conditions having pH of 7.5, N-342.16 kgh<sup>-1</sup>, P-41.93 kgh<sup>-1</sup>, and K-234.24 kgh<sup>-1</sup>. The Broccoli (*Brassica oleracea* var *italica* L.) crop with variety Saki (Fiesta) was sown in the main season, midseason, and late season in the nursery on 12 September 2021, 02 October 2021, and 23 October 2021, respectively. The seeds were sown in well-prepared beds in lines 2-3

cm deep spaced 5 cm apart then covered well with fine soil to facilitate early and uniform germination. Manure completely decompose (FYM) was applied 45 days after transplanting at the rate of 10 kg per bed. Seedlings were ready to transplant in the field after one month of sowing in the nursery from their respective seasons. FYM and fertilizers were applied as per the package of practices for vegetable crops, Directorate of Extension Education, Dr. Y. S. Parmar University of Horticulture and Forestry, Nauni, Solan (HP).

T - Transplanting, M - Mulching, I-Irrigation

The field performance studies on the Effect of weather parameters on biometric parameters and the yield of broccoli. i.e. all parameters recorded at the transplanting, vegetative, heading, and harvesting stages after transplanting the height of six selected and tagged plants were measured. The average was calculated.

Chlorophyll content was estimated by using the method given by (Hiscox and Israeistam 2011). The fresh leaves were chopped to fine pieces under subdued light, 100 mg of chopped leaf samples were placed in vials containing 7 ml of Dimethyl sulphoxide, the vials were incubated at  $65^{\circ C}$  for half an hour, and the extract was then transferred to a graduated test tube and the final volume was made to 10 ml with Dimethyle sulphoxide. The optical density of the above extract was recorded on Spectrophotometer (Model: Spectronic-20) at 645 and 663 nm wavelength against Dimethyle sulphoxide blank.

The total chlorophyll content was calculated by using the formula:

Total chlorophyll (mg – 1) = 
$$\frac{202 \, 3645 + 802 \, 3663}{\text{as } 1000 \, \text{s w}} \times \text{V}$$

Where;

V = volume of extract made

a = length of the light path in the cell (usually 1cm)

w = weight of the sample taken

A645 is an absorbance at 645nm, and A663 is an absorbance of 663nm.

The leaf area index is calculated by dividing the leaf area per plant by the land area occupied by the plant.

The leaf area index was calculated at the time of the different phenological stages.

$$LAI = \frac{Leafarea}{Ground area}$$

Evapotranspiration is the sum of evaporation from the land surface plus transpiration from plants. Evapotranspiration was estimated using the formula given by the Papadakis method: -

$$ET = 0.5262 X (Emax - Emin - 2) X \left(\frac{10}{30}\right)$$

#### Whereas,

Emax: Saturation vapour pressure corresponding to average maximum temperature.

Emin-2: Saturation vapour pressure corresponding to average dew point temperature.

Tmax: Maximum temperature

Tmin: Minimum temperature

Soil temperature recorded 15cm depth was recorded at the minimum 07:30 AM and maximum 02:30 PM hours using a soil thermometer. The soil temperature was recorded at different phenological stages.

Relative humidity under the canopy of the crop (%) Hygrometer, the temperature was recorded at four phenological stages. Humidity on the recorded leaf surface was recorded at the minimum 07:30 AM and maximum 02:30 PM hours on using a hygrometer. The humidity was recorded at different phenological stages. Soil moisture (%) Oven drying method: - Soil sample is collected in a moisture can and the wet weight of the sample is recorded. The soil sample is dried in a hot air oven at 105°C until a constant weight is obtained and the dry weight of the sample is recorded Kelly (2004).

Moisture content (on weight basis) =  $\frac{\text{Fresh weight} - \text{Dry weight}}{\text{Dry weight}} \times 100$

Crop Phenology The periodic biological events and their dates of occurrence in plant life in relation to the influence of weather are called phenology. The number of days taken by each phenophase.

The periodic biological events and their dates of occurrence in plant life with the influence of weather are called phenology.

Growing degree days (GDD)The degree-day or heat unit is the departure from the mean daily temperature above the minimum threshold or base temperature or critical temperature or it is the difference between the daily mean temperature and base temperature.

Growing degree days is calculated as

$$GDD = \frac{Tmax + Tmin}{2}$$
 – Where, Tb is base

temperature of crop

Helio-thermal units (HTU) the Product of GDD and the number of actual bright sunshine hours on the day is called helio-thermal unit (HTU).

Helio-thermal units are calculated as a formula: -

 $HTU = GDD \times Sunshine hours$ 

Photo-thermal units (PTU)The product of GDD and maximum bright sunshine hours of any day is called a photo thermal unit.

Photo-thermal units are calculated as

 $PTU = GDD \times Day length$ 

**Statistical Analysis.** The data recorded were analyzed by using MS Excel, and OPSTAT. The mean values of each replication for all the traits under study were subjected to statistical analysis as per Randomized Complete Block Design (Factorial).

# **RESULTS AND DISCUSSION**

The results obtained are presented character-wise as follows

# A. Chlorophyll content (mg/g)

Chlorophyll content (mg/g) increased with the advancement of the plant age. The maximum chlorophyll content was estimated in  $T_2$  (2.23 mg/g) followed by  $T_1$  (1.91 mg/g) and  $T_3$  (1.63 mg/g) at the heading stage which results in a higher yield per plot in  $T_2$  (10.44 kg) followed by  $T_1$  (8.58 kg) and  $T_3$  (6.35 kg) under different environmental conditions. While maximum chlorophyll content was estimated with the application of mulch  $M_1$  (2.13 mg/g) during the heading stage as compared to no mulch treatment  $M_2$  (1.73) mg/g) which resulted in a higher yield per plot in  $M_1$ (9.71 kg) followed by  $M_2$  (7.21 kg). The chlorophyll content was maximum due to the application of irrigation I<sub>2</sub> (2.01 mg/g) at the heading stage as compared to rainfed conditions  $I_1$  (1.84 mg/g) which resulted in a higher yield in  $I_1$  (9.17 kg) followed by  $I_2$ (7.76 kg).

The combined effect of interaction for second transplanting (T<sub>2</sub>), with mulch (M<sub>1</sub>) and good irrigation conditions (I<sub>1</sub>), showed maximum chlorophyll content in T<sub>2</sub>M<sub>1</sub> (2.53 mg/g), T<sub>2</sub>I<sub>2</sub> (2.35 mg/g), M<sub>1</sub>I<sub>2</sub> (2.27 mg/g) and T<sub>2</sub>M<sub>1</sub>I<sub>2</sub> (2.68 mg/g), while the minimum in third transplanting (T<sub>3</sub>), with no mulch (M<sub>2</sub>) and rainfed (I<sub>2</sub>) conditions, were T<sub>3</sub>M<sub>2</sub> (1.50 mg/g), T<sub>3</sub>I<sub>2</sub> (1.56 mg/g), M<sub>2</sub>I<sub>1</sub> (1.70 mg/g) and T<sub>3</sub>M<sub>2</sub>I<sub>2</sub> (1.26 mg/g). Similar findings were also recorded by Conversa *et al.* (2020). They obtained the chlorophyll contents (2.21mg/g) and (1.21mg/g) for black mulch in the initial heading and harvesting stages respectively. A relationship between chlorophyll and leaf area index in higher chlorophyll content was also recorded Table 1.

The maximum yield per plot was obtained in the combined effect of interaction for second transplanting (T<sub>2</sub>), with mulch (M<sub>1</sub>) and good irrigation conditions (I<sub>2</sub>) i.e., T<sub>2</sub>M<sub>1</sub> (12.36 kg), T<sub>2</sub>I<sub>1</sub> (11.39 kg), M<sub>1</sub>I<sub>1</sub> (10.48 kg) and T<sub>2</sub>M<sub>1</sub>I<sub>1</sub> (13.29 kg), while minimum in third transplanting (T<sub>3</sub>), with no mulch (M<sub>2</sub>) and rainfed (I<sub>2</sub>) conditions i.e., T<sub>3</sub>M<sub>2</sub> (5.49 kg), T<sub>3</sub>I<sub>2</sub> (5.74 kg), M<sub>2</sub>I<sub>2</sub> (6.56 kg) and T<sub>3</sub>M<sub>2</sub>I<sub>2</sub> (5.19 kg). Moreover, the yield per plot obtained in the control was significantly less (5.10 kg) as compared to the interactions.

The maximum ET was estimated in  $T_3$  (2.50mm) during the harvesting stage due to high temperature, followed by  $T_2$  (2.48mm) and  $T_1$  (2.38mm) at different transplanting stages and the higher yield per plot was obtained in  $T_2$  (10.44kg) followed by  $T_1$  (8.58kg) and  $T_3$  (6.35kg) due to suitable climatic conditions. While maximum ET was estimated with the application of mulch  $M_1$  (2.53mm) during the transplanting stage as compared to no mulch treatment  $M_2$  (2.26mm) during the harvesting stage which results in a higher yield per plot in M1 (9.71kg) followed by  $M_2$  (7.21kg). Table 2.

The ET was maximum due to the application of irrigation in I<sub>1</sub> (2.48mm) at the harvesting stage as compared to rainfed conditions I<sub>2</sub> (2.27mm) at the transplanting stage which resulted in a higher yield in I<sub>1</sub> (9.17kg) followed by I<sub>2</sub> (7.76kg). The black polythene mulch performed well as compared to no mulch irrespective of irrigation treatments. These results support the findings of Thentu *et al.* (2016). They obtained an ET of 1.68mm and found a significantly higher effect of black polythene mulch and irrigation on ET in broccoli.

The maximum yield per plot was obtained in the combined effect of interaction for second transplanting (T<sub>2</sub>), with mulch (M<sub>1</sub>) and good irrigation conditions (I<sub>1</sub>) i.e., T<sub>2</sub>M<sub>1</sub> (12.36kg), T<sub>2</sub>I<sub>1</sub> (11.39kg), M<sub>1</sub>I<sub>1</sub> (10.48kg) and T<sub>2</sub>M<sub>1</sub>I<sub>1</sub> (13.29kg), while minimum in third transplanting (T<sub>3</sub>), with no mulch (M<sub>2</sub>) and rainfed (I<sub>2</sub>) conditions i.e., T<sub>3</sub>M<sub>2</sub> (5.49kg), T<sub>3</sub>I<sub>2</sub> (5.74), M<sub>2</sub>I<sub>2</sub> (6.56kg) and T<sub>3</sub>M<sub>2</sub>I<sub>2</sub> (5.19kg). Moreover, the yield per plot

obtained in the control was significantly less (5.10kg) as compared to the interactions.

#### C. Leaf area index (LAI)

The maximum leaf area index was recorded in  $T_2$  (5.10) followed by  $T_1$  (4.19) and  $T_3$  (3.03) at the harvesting stage. While the maximum leaf area index was obtained with the application of mulch  $M_1$  (4.41) at the harvesting stage and the minimum was obtained with no mulch treatment  $M_2$  (3.80). The variations in leaf area index under different irrigation treatments were statistically significant at all growth stages except the transplanting stage under  $I_1$  (4.41) followed by  $I_2$  (3.80) at the harvesting stage. Table 3.

The interaction between various factors under study was found to be non-significant at the transplanting stage for leaf area index but significant at other vegetative, heading, and harvesting stages. The combined effect of interaction for second transplanting ( $T_2$ ), with mulch ( $M_1$ ) and good irrigation conditions ( $I_1$ ), showed maximum leaf area index in  $T_2M_1$  (5.58),

| Meena et al., Biological Forum – An International Journal | 15(2): 894-908(2023) | 900 |
|---|----------------------|-----|
|---|----------------------|-----|

 $T_2I_1$  (5.41),  $M_1I_1$  (4.74) and  $T_2M_1I_1$  (5.87), while minimum leaf area index in third transplanting (T<sub>3</sub>),

with no mulch (M<sub>2</sub>) and rainfed (I<sub>2</sub>) conditions, were  $T_3M_2$  (2.79),  $T_3I_2$  (2.67),  $M_2I_2$  (3.36) and  $T_3M_2I_2$  (2.54).

Table 3: Leaf area index during different phenophase of broccoli.

The maximum yield per plot was obtained in the combined effect of interaction for second transplanting  $(T_2)$ , with mulch  $(M_1)$  and good irrigation conditions  $(I_1)$  i.e.,  $T_2M_1$  (12.36kg),  $T_2I_1$  (11.39kg),  $M_1I_1$  (10.48kg) and  $T_2M_1I_1$  (13.29kg), while the minimum in third transplanting  $(T_3)$ , with no mulch  $(M_2)$  and rainfed  $(I_2)$ conditions i.e., T<sub>3</sub>M<sub>2</sub> (5.49kg), T<sub>3</sub>I<sub>2</sub> (5.74), M<sub>2</sub>I<sub>2</sub> (6.56kg) and  $T_3M_2I_2$  (5.19kg). Also, the yield per plot obtained in the control was significantly lowered (5.10kg) as compared to the interactions. Olfati et al. (2010) showed a significant difference in leaf area index (LAI) Meena et al.,

for black mulch having a profound effect on plant growth, which resulted in an increase in the LAI for various growth stages.

#### D. Soil temperature

The soil temperature was recorded at different stages; transplanting, vegetative, heading, and harvesting. It is apparent from the data presented in Table 4 that during the transplanting stage, the maximum soil temperature was recorded in  $T_1M_1I_2$  (31.73°C) and the minimum in  $T_3M_1I_1$  (7.83°C). While during the vegetative stage, the

Biological Forum – An International Journal 15(2): 894-908(2023)

maximum soil temperature was recorded in  $T_1M_1I_2$  (22.50 °C) and the minimum in  $T_2M_1I_2$  (5.13 °C). During the heading stage, the maximum soil temperature was recorded in  $T_3M_1I_2$  (17.00 °C) and the

minimum in  $T_1M_2I_2$  (6.50 °C). The maximum temperature during the harvesting stage was found in  $T_3M_1I_2$  (25.63 °C) and the minimum in  $T_1M_2I_2$  (10.00°C).

Table 4: Soil temperature (°C) during different phenophase of broccoli.

In control, during the transplanting stage, the maximum soil temperature was found to be (23.89 °C) and the minimum was (21.33 °C) while during the vegetative stage, the maximum soil temperature was (18.56 °C) and the minimum was (9.26 °C). During the heading stage, the maximum soil temperature was found to be (12.86 °C) and the minimum was (6.12 °C). The maximum temperature during the harvesting stage was found to be (17.89 °C) and the minimum was (11.26 °C). Sharma (2009) observed 28°C and 16°C as the highest and lowest soil temperatures for black mulch treatment respectively which could be due to the reduced evaporation and minimum heat loss from the soil surface.

*E.* Relative humidity recorded under the canopy of the crop

It is apparent from the data presented in Table 5 that during the transplanting stage, the maximum relative humidity was recorded in  $T_1M_1I_2$  (61.13%) and the minimum in  $T_3M_2I_2$  (29.78%). While during the vegetative stage, the maximum relative humidity was recorded in  $T_3M_1I_2$  (62.1%) and the minimum in  $T_2M_2I_2$ (40.5%). During the heading stage, the maximum relative humidity was recorded in  $T_2M_1I_1$  (64.77%) and the minimum in  $T_1M_2I_2$  (34.5%). The maximum relative humidity during the harvesting stage was found in  $T_1M_1I_1$  (84.97%) and the minimum in  $T_3M_2I_2$ (32.54%).

In control, during the transplanting stage, the maximum relative humidity was found to be (53.23%) and the minimum was (45.75%) while during the vegetative stage, the maximum relative humidity was (48.00%) and the minimum was (41.23%). During the heading stage, the maximum relative humidity was found to be (45.89%) and the minimum was (44.82%). The maximum relative humidity during the harvesting stage was found to be (69.87%) and the minimum was (66.23%). A similar finding was observed by Tibbitts (1979) who obtained relative humidity (56.23%) due to the effect of black mulch treatment.

#### F. Soil moisture

It is apparent from the data presented in Table 6 that the maximum soil moisture was obtained in  $T_1M_1I_1$ (72.63%) at the harvesting stage and the minimum in  $T_2M_1I_1$  (20.76%) at the transplanting stage. During control, the maximum soil moisture was obtained in the heading stage (44.13%) while the minimum was in the transplanting stage (24.42%). Verma *et al.* (2018) found that soil moisture plays an important role in the growth and development of the crop. They found 53.2 percent and 15.7 percent as the highest and lower soil moisture

# Table 6: Soil moisture (%) during different phenophase of broccoli.

## G. Crop phenology

Maximum number of days was recorded in  $T_2$  (132 days) followed by  $T_1$  (104 days) and  $T_3$  (94 days) at the harvesting stage. While with the application of mulch  $M_1$ , the number of days taken to reach the harvesting stage was (111 days), and with no mulch treatment  $M_2$ 

(109 days). The variations in crop phenology under different irrigation treatments were statistically significant at both the growth stages under  $I_1$  (110 days) and followed by  $I_2$  (109 days) at the harvesting stage. Table 7.

| Treatment                     | Crop phenology |         |            |            |  |  |

The combined effect of interaction for second transplanting  $(T_2)$  with mulch  $M_1$  and good irrigation conditions (I<sub>1</sub>), has taken a maximum number of days as in T<sub>2</sub>M<sub>1</sub> (132 days), T<sub>2</sub>I<sub>1</sub> (132 days), M<sub>1</sub>I<sub>1</sub> (112 days),  $T_2M_1I_1$  (132 days) and  $T_2M_1I_2$  (132 days) while minimum in third transplanting (T<sub>3</sub>), with no mulch (M<sub>2</sub>) and rainfed (I<sub>2</sub>) conditions i.e., T<sub>3</sub>M<sub>2</sub> (92 days),  $T_3I_2$  (93 days),  $M_2I_2$  (108 days) and  $T_3M_2I_2$  (91 days). The number of days taken to reach the harvesting stage in control was (101 days) which was significantly minimum as compared to interactions. Similar outcomes on heat requirements for attaining the different phenological stages in broccoli were also reported by Dhankhar et al. (2017). They observed maximum heat requirement for T2 (date of 2nd treatment) because of the long crop harvest duration.

#### H. Growing degree days

It is apparent from the data presented in Table 8 that the maximum growing degree days were recorded in  $T_2$  (940.10 °C Day hours) followed by  $T_1$  (921.38 °C Day

hours) and T<sub>3</sub> (569.86 °C Day hours) at the harvesting stage which resulted in a higher yield per plot in T<sub>2</sub> (10.44kg) followed by  $T_1$  (8.58kg) and  $T_3$  (6.35kg). While maximum growing degree days were obtained with the application of mulch  $M_1$  (816.75°C Day hours) at the harvesting stage and minimum with no mulch treatment M<sub>2</sub> (804.14°C Day hours) during the harvesting stage which resulted in a higher yield per plot in  $M_1$  (9.71kg) followed by  $M_2$  (7.21kg). The variations in growing degree days under different irrigation treatments were statistically non-significant at the vegetative stage but significant at other growth stages under I<sub>1</sub> (816.75°C Day hours) followed by I<sub>2</sub> (804.14°C Day hours) at the harvesting stage which resulted in a higher yield in  $I_1$  (9.17kg) followed by  $I_2$ (7.76kg). A similar finding of growing degree days (970.6°C Day hours) was also observed by Dhankhar et al. (2017) which could be due to the long crop harvest duration

The maximum yield per plot was obtained in the combined effect of interaction for second transplanting (T<sub>2</sub>), with mulch (M<sub>1</sub>) and good irrigation conditions (I<sub>1</sub>) i.e., T<sub>2</sub>M<sub>1</sub> (12.36kg), T<sub>2</sub>I<sub>1</sub> (11.39kg), M<sub>1</sub>I<sub>1</sub> (10.48kg) and T<sub>2</sub>M<sub>1</sub>I<sub>1</sub> (13.29kg), while minimum in third transplanting (T<sub>3</sub>), with no mulch (M<sub>2</sub>) and rainfed (I<sub>2</sub>) conditions i.e., T<sub>3</sub>M<sub>2</sub> (5.49kg), T<sub>3</sub>I<sub>2</sub> (5.74), M<sub>2</sub>I<sub>2</sub> (6.56kg) and T<sub>3</sub>M<sub>2</sub>I<sub>2</sub> (5.19kg). Also, the yield per plot obtained in the control was significantly less (5.10kg) as compared to the interactions.

# I. Helio-thermal units

It is apparent from the data presented in Table 9 that the maximum helio-thermal units were recorded in  $T_1$  (7248.74°C Day hours) followed by  $T_2$  (6926.32°C Day hours) and  $T_3$  (3939.68°C Day hours) at the harvesting stage which resulted in a higher yield per plot in  $T_2$ 

(10.44kg) followed by  $T_1$  (8.58kg) and  $T_3$  (6.35kg). While maximum helio-thermal units were recorded with the application of mulch  $M_1$  (6111.38°C Day hours) during the harvesting stage as compared to no mulch treatment  $M_2$  (5965.11°C Day hours) during the harvesting stage which resulted in a higher yield per plot in  $M_1$  (9.71kg) followed by  $M_2$  (7.21kg). The helio-thermal units were maximum due to the application of irrigation i.e., in  $I_1$  (6084.23°C Day hours) at the harvesting stage as compared to rainfed conditions  $I_2$  (5992.26°C Day hours) at the harvesting stage which resulted in a higher yield in  $I_1$  (9.17kg) followed by  $I_2$  (7.76kg). Similar findings with helio-thermal units of 5866.5 and 6136.9°C Day hours were also observed by Dhankhar *et al.* (2017).

Table 9: Helio-thermal units (°C Day h) during different phenophase of broccoli.

The maximum yield per plot was obtained in the combined effect of interaction for second transplanting (T<sub>2</sub>), with mulch (M<sub>1</sub>) and good irrigation conditions (I<sub>1</sub>) i.e.,  $T_2M_1$  (12.36kg),  $T_2I_1$  (11.39kg),  $M_1I_1$  (10.48kg) and  $T_2M_1I_1$  (13.29kg), while minimum in third transplanting (T<sub>3</sub>), with no mulch (M<sub>2</sub>) and rainfed (I<sub>2</sub>) conditions i.e.,  $T_3M_2$  (5.49kg),  $T_3I_2$  (5.74kg),  $M_2I_2$  (6.56kg) and  $T_3M_2I_2$  (5.19kg). Also, the yield per plot obtained in the control was significantly less (5.10kg) as compared to the interactions.

#### J. Photo-thermal units

It is apparent from the data presented in Table 10 that the maximum photo-thermal units were recorded in  $T_1$ (10031.55°C Day hours) followed by  $T_2$  (9926.56°C Day hours) and  $T_3$  (5843.28°C Day hours) at the harvesting stage which resulted in a higher yield per plot in T<sub>2</sub> (10.44kg) followed by T<sub>1</sub> (8.58kg) and T<sub>3</sub> (6.35kg). While maximum photo-thermal units were recorded with the application of mulch M<sub>1</sub> (8700.23 °C Day hours) during the harvesting stage as compared to no mulch treatment M<sub>2</sub> (8500.69 °C Day hours) which resulted in a higher yield per plot in M<sub>1</sub> (9.71kg) followed by M<sub>2</sub> (7.21kg). The photo-thermal units were recorded maximum due to the application of irrigation i.e., in I<sub>1</sub> (8600.67 °C Day hours) at the harvesting stage as compared to rainfed conditions I<sub>2</sub> (8540.26 °C Day hours) at the transplanting stage which resulted in a higher yield per plot in I<sub>1</sub> (9.17kg) followed by I<sub>2</sub> (7.76kg). A similar finding of 10214.9 °C Day hours photo-thermal units was also observed by Dhankhar *et al.* (2017).

Table 10: Photo-thermal units (°C Day h) during different phenophase of broccoli.

| Treatment             |            | Photo-thermal units |            | W-14/-1-4 (1)   |

The maximum yield per plot was obtained in the combined effect of interaction for second transplanting  $(T_2)$ , with mulch  $(M_1)$  and good irrigation conditions  $(I_1)$  i.e.,  $T_2M_1$  (12.36kg),  $T_2I_1$  (11.39kg),  $M_1I_1$  (10.48kg) and  $T_2M_1I_1$  (13.29kg), while minimum in third transplanting  $(T_3)$ , with no mulch  $(M_2)$  and rainfed  $(I_2)$ conditions i.e., T<sub>3</sub>M<sub>2</sub> (5.49kg), T<sub>3</sub>I<sub>2</sub> (5.74), M<sub>2</sub>I<sub>2</sub> (6.56kg) and  $T_3M_2I_2$  (5.19kg). Also, the yield per plot obtained in the control was significantly less (5.10kg) as compared to the interactions.

#### CONCLUSIONS

The present study revealed that 2<sup>nd</sup> date of sowing, mulching, and irrigation had a significant effect on the vield of broccoli (208g/ha). The crop transplanted on October 28 took a maximum of days to attain different phenological stages and accumulated the maximum number of growing days and heat units which were reduced with the subsequent delay in transplanting. The mulching and irrigation played an important role in the physiological and morphological characteristics of broccoli thus enhance the crop yield. Hence, treatment T<sub>2</sub>M<sub>1</sub>I<sub>1</sub> is recommended for improving morphological characteristics, yield attributes and biometric attributes, under different environmental conditions in Broccoli.
